### Why Matrix Algebra?

Data:

$$X = \begin{bmatrix} x_{11} & x_{12} & \cdots & x_{1p} \\ x_{21} & x_{22} & \cdots & x_{2p} \\ \vdots & \cdots & \cdots & \vdots \\ x_{n1} & x_{n2} & \cdots & x_{np} \end{bmatrix}$$

Summary Statistics:

$$\bar{X} = \begin{bmatrix} \bar{x}_1 \\ \bar{x}_2 \\ \vdots \\ \bar{x}_p \end{bmatrix} = \begin{bmatrix} \frac{1}{n} \sum_{i=1}^n x_{i1} \\ \frac{1}{n} \sum_{i=1}^n x_{i2} \\ \vdots \\ \frac{1}{n} \sum_{i=1}^n x_{ip} \end{bmatrix} = \frac{1}{n} X^T \mathbf{1}$$

is the **sample mean vector**,

$$\text{and } S = \begin{bmatrix} s_{11} & s_{12} & \cdots & s_{1p} \\ s_{21} & s_{22} & \cdots & s_{2p} \\ \vdots & \cdots & \cdots & \cdots \\ s_{p1} & s_{p2} & \cdots & s_{pp} \end{bmatrix} = \frac{1}{n-1} X^T \left( I - \frac{1}{n} \mathbf{1}\mathbf{1}^T \right) X$$

is the **sample covariance matrix**. Many matrix algebra techniques will be applied to this matrix in multivariate analysis

## Covariance Matrices

- **Covariance Matrix**

$$\Sigma = \underbrace{\begin{bmatrix} \sigma_{11} & \sigma_{12} & \cdots & \sigma_{1p} \\ \sigma_{21} & \sigma_{22} & \cdots & \sigma_{2p} \\ \vdots & \vdots & \ddots & \vdots \\ \sigma_{p1} & \sigma_{p2} & \cdots & \sigma_{pp} \end{bmatrix}}_{\text{population covariance matrix}}, \quad \mathbf{S} = \underbrace{\begin{bmatrix} s_{11} & s_{12} & \cdots & s_{1p} \\ s_{21} & s_{22} & \cdots & s_{2p} \\ \vdots & \vdots & \ddots & \vdots \\ s_{p1} & s_{p2} & \cdots & s_{pp} \end{bmatrix}}_{\text{sample covariance matrix}}$$

- Since  $\sigma_{jk} = \sigma_{kj}$  (likewise  $s_{jk} = s_{kj}$ ) for all  $j \neq k \Rightarrow \Sigma$  and  $S$  are **symmetric**
- $\Sigma$  and  $S$  are also **non-negative definite**

## Vectors

- A column array of  $p$  elements is called a **vector** of dimension  $p$  and is written as

$$\mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_p \end{bmatrix}$$

- The **transpose** of the column vector  $x$  is a row vector

$$\mathbf{x}^T = [x_1 \quad x_2 \quad \cdots \quad x_p]$$

- $L_x^{-1}\mathbf{x}$ , where  $L_x = \sqrt{\sum_{j=1}^p x_j^2}$ , is called a **unit vector**

## Matrices

- A matrix  $A$  is an array of elements  $a_{ij}$  with  $n$  rows and  $p$  columns:

$$A = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1p} \\ a_{21} & a_{22} & \cdots & a_{2p} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{np} \end{bmatrix}$$

- The transpose  $A^T$  has  $p$  rows and  $n$  columns. The  $j$ -th row of  $A^T$  is the  $j$ -th column of  $A$

$$A^T = \begin{bmatrix} a_{11} & a_{21} & \cdots & a_{n1} \\ a_{12} & a_{22} & \cdots & a_{n2} \\ \vdots & \vdots & \ddots & \vdots \\ a_{1p} & a_{2p} & \cdots & a_{np} \end{bmatrix}$$

## Identity Matrix and Inverse Matrix

- An **identity matrix**, denoted by  $I$ , is a square matrix with 1's along the diagonal and 0's everywhere else. For example

$$I_{3 \times 3} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

- Consider two square matrices  $A$  and  $B$  with the same dimension. If

$$AB = BA = I,$$

then  $B$  is the **inverse** of  $A$ , denoted by  $A^{-1}$

## Orthogonal Matrices

- A square matrix  $Q$  is **orthogonal** if

$$QQ^T = Q^TQ = I$$

- If  $Q$  is orthogonal, its rows and columns have unit length (i.e.,  $L_{q_j} = 1$ ) and are mutually perpendicular (i.e.,  $q_j^T q_k = 0$  for any  $j \neq k$ )

- **Example:**

$$Q = \frac{1}{3} \begin{bmatrix} 2 & -2 & 1 \\ 1 & 2 & 2 \\ 2 & 1 & -2 \end{bmatrix}$$

## Eigenvalues and Eigenvectors

- A square matrix  $A$  has an eigenvalue  $\lambda$  with corresponding eigenvector  $x \neq 0$  if

$$Ax = \lambda x.$$

The eigenvalues of  $A$  are the solution to  $|A - \lambda I| = 0$

- A normalized eigenvector is denoted by  $e$  with  $e^T e = 1$
- A  $p \times p$  matrix  $A$  has  $p$  pairs of eigenvalues and eigenvectors

$$\lambda_1, e_1 \quad \lambda_2, e_2 \quad \cdots \quad \lambda_p, e_p$$

## Spectral Decomposition

- Eigenvalues and eigenvectors will play an important role in DSA 8070. For example, **principal components** are based on the eigenvalues and eigenvectors of **sample covariance matrices**
- The **spectral decomposition** of a  $p \times p$  symmetric matrix  $A$  is  $A = \lambda_1 e_1 e_1^T + \lambda_2 e_2 e_2^T + \dots + \lambda_p e_p e_p^T$ . This can be written in the following matrix form:

$$\underbrace{\begin{bmatrix} e_1 & e_2 & \dots & e_p \end{bmatrix}}_P \underbrace{\begin{bmatrix} \lambda_1 & 0 & \dots & 0 \\ 0 & \lambda_2 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & \lambda_p \end{bmatrix}}_A \underbrace{\begin{bmatrix} e_1 & e_2 & \dots & e_p \end{bmatrix}^T}_{P^T}$$

## Determinant and Trace

- The **trace** of a  $p \times p$  matrix  $A$  is the sum of the diagonal elements, i.e.,  $\text{trace}(A) = \sum_{i=1}^p a_{ii}$
- The trace of a square, symmetric matrix  $A$  is the **sum of the eigenvalues**, i.e.,  $\text{trace}(A) = \sum_{i=1}^p a_{ii} = \sum_{i=1}^p \lambda_i$
- The **determinant** of a square, symmetric matrix  $A$  is the product of the eigenvalues, i.e.,  $|A| = \prod_{i=1}^p \lambda_i$

## Positive Definite Matrix

- For a  $p \times p$  symmetric matrix  $A$  and a vector  $x = [x_1 \ x_2 \ \dots \ x_p]^T$  the quantity  $x^T A x = \sum_{i=1}^p \sum_{j=1}^p a_{ij} x_i x_j$  is called a **quadratic form**
- If  $x^T A x \geq 0$  for any vector  $x$ , both  $A$  and the quadratic form are said to be **non-negative definite**  
 $\Rightarrow$  **all the eigenvalues of  $A$  are non-negative**
- If  $x^T A x > 0$  for any vector  $x \neq 0$ , both  $A$  and the quadratic form are said to be **positive definite**  
 $\Rightarrow$  **all the eigenvalues of  $A$  are positive**

## Square-Root Matrices

- Spectral decomposition of a positive definite matrix  $A$  yields

$$A = \sum_{j=1}^p \lambda_j e_j e_j^T = P \Lambda P^T,$$

with  $\Lambda_{p \times p} = \text{diag}(\lambda_j)$ , all  $\lambda_j > 0$ , and  $P_{p \times p} = [e_1 \ e_2 \ \dots \ e_p]$  an orthonormal matrix of eigenvectors. Then

$$A^{-1} = P \Lambda^{-1} P^T = \sum_{j=1}^p \frac{1}{\lambda_j} e_j e_j^T$$

- With  $\Lambda^{\frac{1}{2}} = \text{diag}(\lambda_j^{\frac{1}{2}})$ , a square-root matrix is

$$A^{\frac{1}{2}} = P \Lambda^{\frac{1}{2}} P^T = \sum_{j=1}^p \sqrt{\lambda_j} e_j e_j^T$$

## Partitioning Random vectors

- If we partition the  $p \times 1$  random vector  $X$  into two components  $X_1, X_2$  of dimensions  $q \times 1$  and  $(p - q) \times 1$  respectively, then the mean vector and the variance-covariance matrix need to be partitioned accordingly

- Partitioned mean vector:

$$\mathbb{E}[X] = \mathbb{E} \begin{bmatrix} X_1 \\ X_2 \end{bmatrix} = \begin{bmatrix} \mathbb{E}[X_1] \\ \mathbb{E}[X_2] \end{bmatrix} = \begin{bmatrix} \mu_1 \\ \mu_2 \end{bmatrix}$$

- Partitioned covariance matrix:

$$\Sigma = \begin{bmatrix} \text{Var}(X_1) & \text{Cov}(X_1, X_2) \\ \text{Cov}(X_2, X_1) & \text{Var}(X_2) \end{bmatrix} = \begin{bmatrix} \underbrace{\Sigma_{11}}_{q \times q} & \underbrace{\Sigma_{12}}_{q \times (p-q)} \\ \underbrace{\Sigma_{21}}_{(p-q) \times q} & \underbrace{\Sigma_{22}}_{(p-q) \times (p-q)} \end{bmatrix}$$

## Summary

In this lecture, we learned about some matrix concepts, facts, and tools that are useful for multivariate data analysis.

In the next lecture, we will learn:

- Multivariate Normal Distribution
- Copula
- Non-parametric Density Estimation
