### Dog Experiment [Source: PSU STAT 505]

A completely randomized block design was carried out to determine the effects of 4 surgical treatments on coronary potassium in a group of 36 dogs. There are 9, 8, 9, and 10 dogs in each treatment group, respectively. Each dog was measured at four different time points (1, 5, 9, and 13 minutes) following one of four experimental treatments:

- Control - no surgical treatment is applied
- Extrinsic cardiac denervation immediately prior to treatment
- Bilateral thoracic sympathectomy and stellectomy 3 weeks prior to treatment
- Extrinsic cardiac denervation 3 weeks prior to treatment

We are looking at the treatment effect on the coronary sinus potassium levels

---

---

---

### Notation of Approaches

Let  $Y_{ijk}$  be the potassium level for treatment  $i$  in dog  $j$  at time  $k$ :

- there are  $a = 4$  treatments (i.e.,  $i = 1, 2, 3, 4$ )
- $n_i$  dogs received treatment  $i$  (therefore, there are  $n_1 + \dots + n_a = 9 + 8 + 9 + 10 = 36$  dogs in total)
- $t = 4$ , the number of observations over time (i.e.,  $k = 1, 2, 3, 4$ )

### Approaches

- Split-plot ANOVA
- MANOVA
- Mixed Models

Notes

---

---

---

---

---

---

---

### Approach 1: Split-plot ANOVA

**Model:**  $Y_{ijk} = \mu + \alpha_i + \delta_{j(i)} + \beta_k + (\alpha\beta)_{ik} + \varepsilon_{ijk}$ ,

where

- $\alpha_i$ : effect of treatment  $i$
- $\delta_{j(i)}$ : random effect of dog  $j$  receiving treatment  $i$
- $\beta_k$ : effect of time  $k$
- $(\alpha\beta)_{ik}$ : treatment by time interaction
- $\varepsilon_{ijk}$ : random error

**Assumptions:**

- $\varepsilon_{ijk} \stackrel{i.i.d.}{\sim} N(0, \sigma_\varepsilon^2)$
- $\delta_{j(i)} \stackrel{i.i.d.}{\sim} N(0, \sigma_\delta^2)$
- $\beta_k$  does not depend on the dog  $\Rightarrow$  no time by dog interaction

### Dog Experiment Split-plot Analysis

```
> library(lmerTest)
> fit <- lmer(Response ~ Treatment * Time + (1 | Dog_id), data = dat)
> anova(fit)
Type III Analysis of Variance Table with Satterthwaite's method
  Sum Sq Mean Sq NumDF DenDF F value Pr(>F)
Treatment  3.3396  1.11319    3   32  6.0038  0.002297 **
Time       6.2043  2.06811    3   96 11.1540 2.404e-06 ***
Treatment:Time 3.4397  0.38219    9   96  2.0613  0.040573 *
---
Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

#### Hypothesis Tests:

We start with the interaction between treatment and time:

$$H_0 : (\alpha\beta)_{ik} = 0 \quad \forall i = 1, \dots, a, k = 1, 2, \dots, t$$

**Result:** We conclude the effect of treatment depends on time at  $\alpha = 0.05$  level

---

---

---

---

---

### Interaction Plot

Rejecting  $H_0 : (\alpha\beta)_{ik} = 0$  means we reject the assumption of "parallelism"

### Some Criticisms about the Split-ANOVA Approach

- The Split-plot ANOVA Approach assumes a constant correlation between any two observations from the same dog, that is,  $\text{Cor}(Y_{ijk}, Y_{ijk'}) = \frac{\sigma_{\alpha}^2}{\sigma_{\alpha}^2 + \sigma_{\epsilon}^2}$ , this is the so-called **compound symmetry** correlation structure
- This assumption is unlikely to be valid with repeated measurements over time as the correlation for two nearby time points is likely to be higher than the correlation for two far apart time points
- Next, we are going to take a multivariate approach (MANOVA) as an attempt to address this issue

Repeated Measures Analysis

CLEMSON UNIVERSITY

8.8

### Notes

---

---

---

---

---

---

---

---

### Approach 2: MANOVA

Here we consider the observations over time from the same dog, dog  $j$  receiving treatment  $i$  as a single vector of interest

$$\mathbf{Y}_{ij} = (Y_{ij1}, Y_{ij2}, \dots, Y_{ijt})^T,$$

and we will perform a one-way MANOVA

#### Assumptions:

- Dogs receiving treatment  $i$  have common mean vector  $\mu_i$
- All dogs have common covariance matrix  $\Sigma$
- Data from different dogs are independently sampled
- Data are multivariate normally distributed

---

---

---

---

---

## Dog Experiment MANOVA Analysis

```
> dat <- read.table("dog1.txt")
> out <- manova(cbind(V3, V4, V5, V6) ~ as.factor(V1), data = dat)
> summary(out, test = "Wilks")
              Df  Wilks approx F num Df den Df  Pr(>F)
as.factor(V1)  3 0.48452    2.022   12 77.018 0.03316 *
Residuals     32
---
Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

**Results:** There are significant differences between at least one pair of treatments in at least one measurement of time

**Criticism:** MANOVA makes no assumptions regarding the temporal correlation structure, and hence, may be overparameterized leading to poor parameter estimates

---

---

---

---

---

---

---

---

---

## Approach 3: Mixed Model Analysis

**Main idea:** Split-plot makes a **too restrictive assumption** while **MANOVA** makes **no assumptions** regarding the temporal correlation structure. The mixed model approach allows us to model the temporal correlation involving a limited number of parameters.

**Model:**  $Y_{ijk} = \mu + \alpha_i + \delta_{j(i)} + \beta_k + (\alpha\beta)_{ik} + \varepsilon_{ijk}$ .

**Assumptions:**

- $\varepsilon_{j(ik)} \stackrel{i.i.d.}{\sim} N(0, \sigma_\varepsilon^2)$
- $\delta_{j(i)} \stackrel{i.i.d.}{\sim} N(0, \sigma_\delta^2)$
- The correlation between the errors for the same dog depends only on the difference in observation time points:  $|k - k'|$ , e.g.,  $\text{Cor}(Y_{ijk}, Y_{ijk'}) = \rho^{|k-k'|}$  (Autoregressive with order 1)

## Dog Experiment Mixed Model Analysis

```
> library(nlme)
> fit1 = gls(Response ~ Treatment * Time,
+ correlation = corCompSymm(form = ~ 1 | Dog_id), data = dat2)
> fit2 = gls(Response ~ Treatment * Time,
+ correlation = corAR1(form = ~ 1 | Dog_id), data = dat2)
> anova(fit1, fit2)
      Model df      AIC      BIC    logLik
fit1     1  18 275.8063 327.1429 -119.9032
fit2     2  18 277.5811 328.9177 -120.7906
```

**Results:**

- Based on both AIC/BIC, having an AR(1) does not necessarily improve the model fit (in this data)
- However, having the option of modeling repeated measurement error structure can be useful in general as it provides additional modeling choices

## Summary

In this lecture, we learned about three approaches to analyze repeated measurements:

- Split-plot ANOVA
- MANOVA
- Mixed Effects Model

In the next lecture, we will learn about [Principal Components Analysis](#)
