Hierarchical Clustering

Model-Based
Clustering

Agenda

- 1 Overview
- 2 K-Means Clustering
- 3 Hierarchical Clustering
- 4 Model-Based Clustering

What is Cluster Analysis?

- **Cluster:** a collection of data objects
 - “Similar” to one another within the same cluster
 - “Dissimilar” to the objects in other clusters
- **Cluster analysis:** grouping a set of data objects into clusters
- Clustering is **unsupervised** classification, unlike classification, there is no predefined classes, and the number of clusters is usually unknown

Some Examples of Clustering Applications

- **Market Segmentation:** Help marketers discover distinct groups in their customer bases, and then use this knowledge to develop targeted marketing programs
- **Clustering Gene Expression Data:**

What Is Good Clustering?

- A good clustering method will produce clusters with
 - high within-class similarity
 - low between-class similarity

For example, one can use the **Euclidean distance**

$d(\mathbf{x}_i, \mathbf{x}_j) = \sqrt{\sum_{k=1}^p [x_{i,k} - x_{j,k}]^2}$ to quantify the similarity

- The quality of a clustering result depends on both the similarity measure used and its implementation
- The performance of a clustering method is measured by its ability to discover the hidden patterns

- **Partitioning algorithm:** partition the observations into a pre-specified number of clusters, for example, [K-means clustering](#)
- **Hierarchy algorithm:** Construct a hierarchical decomposition of the observations to build a hierarchy of clusters, for example, [hierarchical agglomerative clustering](#)
- **Model-based Clustering:** A model is hypothesized for each of the clusters, for example, [Gaussian mixture models](#)

Partitioning Algorithm

Let C_1, \dots, C_K denote sets containing the indices of the observations $\{\mathbf{x}_i\}_{i=1}^n$ in each cluster. These sets satisfy two properties:

- $C_1 \cup C_2 \cup \dots \cup C_K = \{1, \dots, n\} \Rightarrow$ each observation belongs to at least one of the K clusters
- $C_k \cap C_{k'} = \emptyset \forall k \neq k' \Rightarrow$ no observation belongs to more than one cluster

For instance, if the i_{th} observation (i.e. \mathbf{x}_i) is in the k_{th} cluster, then $i \in C_k$

The K-Means Algorithm

- **Step 0:** Choose the number of clusters K
- **Step 1:** Randomly assign a cluster (from 1 to K), to each of the observations. These serve as the initial cluster assignments
- **Step 2:** Iterate until the cluster assignment stop changing
 - For each of the K cluster, compute the cluster **centroid**. The k_{th} cluster centroid is the mean vector of the observations in the k_{th} cluster
 - Assign each observations to the cluster whose centroid is closest in terms of Euclidean distance

K-Means Clustering in R

```
kmean3.faithful <- kmeans(x = faithful, centers = 3)
```

Overview

K-Means Clustering

Hierarchical Clustering

Model-Based
Clustering

K = 2

K = 3

K = 4

- k-means clustering requires us to pre-specify the number of clusters K
- **Hierarchical clustering** is an alternative approach which does not require that we commit to a particular choice of K
- **Agglomerative clustering**: This is a “bottom-up” approach: each observation starts in its own cluster, and pairs of clusters are merged as one moves up the hierarchy

Hierarchical Clustering Algorithm

- 1 Begin with n observations and a similarity measure (e.g., Euclidean distance) of all the $\binom{n}{2} = \frac{n(n-1)}{2}$ pairwise dissimilarities. Treat each observation as its own cluster
- 2 For $i = n, n - 1, \dots, 2$;
 - Examine all pairwise inter-cluster dissimilarities among the i clusters and identify the pair of clusters that are least dissimilar. Fuse these two clusters.
 - Compute the new pairwise inter-cluster dissimilarities among the $i - 1$ remaining clusters.

Hierarchical Agglomerative Clustering Illustration

Recap: Hierarchical Agglomerative Clustering Algorithm

- 1 Start with each observation in its own cluster
- 2 Identify the closest two clusters and merge them
- 3 Repeat
- 4 Ends when all observations are in a single cluster

Hierarchical Agglomerative Clustering in R

```
hc.fairful <- hclust(dist(fairful_sample))  
plot(hc.fairful)
```

Hierarchical Clustering

Model-Based
Clustering

Cluster Dendrogram

Model-based clustering

- One disadvantage of K-means is that they are largely heuristic and not based on formal statistical models. Formal inference is not possible
- **Model-based clustering** is an alternative:
 - Sample observations arise from a mixture distribution of two or more components
 - Each component (cluster) is described by a probability distribution and has an associated probability in the mixture.
 - In **Gaussian mixture models**, we assume each cluster follows a multivariate normal distribution

Fitting a Gaussian Mixture Model in R

```
library(mclust)
```

```
## Package 'mclust' version 5.4.5  
## Type 'citation("mclust")' for citing this R package in publications.
```

```
BIC <- mclustBIC(faithful)  
modell <- Mclust(faithful, x = BIC)
```

Model-Based Clustering Analysis for Iris Data

In this lecture we learned about some commonly used clustering methods:

- K-means clustering
- Hierarchical clustering
- Model-based clustering
