## Estimation of the Mean and Autocovariance Function of Stationary Processes

### Mean Estimation

Given a stationary process  $\{\eta_t\}_{t=1}^T$ , the point estimator is  $\bar{\eta} = \frac{1}{T} \sum_{t=1}^T \eta_t$ . The variance of this estimator is

$$\nu_T = \text{Var}(\bar{\eta}) = \text{Var}\left(\frac{1}{T} \sum_{t=1}^T \eta_t\right) = \frac{1}{T} \sum_{h=-(T-1)}^{T-1} \left(1 - \frac{|h|}{T}\right) \gamma(h)$$

*Sample ACF*

$$\hat{\rho}(h) = \frac{\hat{\gamma}(h)}{\hat{\gamma}(0)},$$

where  $\hat{\gamma}(h) = \frac{1}{T} \sum_{t=1}^{T-|h|} (\eta_t - \bar{\eta})(\eta_{t+h} - \bar{\eta})$ .

### Box test for temporal independence

**Box and Pierce test Box and Pierce (1970)**

We wish to test:

$$H_0 : \{\eta_1, \eta_2, \dots, \eta_T\} \text{ is an i.i.d. noise sequence}$$

$$H_1 : H_0 \text{ is false}$$

- Under  $H_0$ ,

$$\hat{\rho}(h) \stackrel{\sim}{\sim} N(0, \frac{1}{T}) \stackrel{d}{=} \frac{1}{\sqrt{n}} N(0, 1)$$

- Hence

$$Q = T \sum_{i=1}^k \hat{\rho}^2(h) \stackrel{\sim}{\sim} \chi_{df=k}^2$$

- We reject  $H_0$  if  $Q > \chi_k^2(1 - \alpha)$ , the  $1 - \alpha$  quantile of the chi-squared distribution with  $k$  degrees of freedom

### Ljung-Box Test

$$Q_{LB} = T(T-2) \sum_{h=1}^k \frac{\hat{\rho}^2(h)}{n-h} \stackrel{\sim}{\sim} \chi_k^2.$$

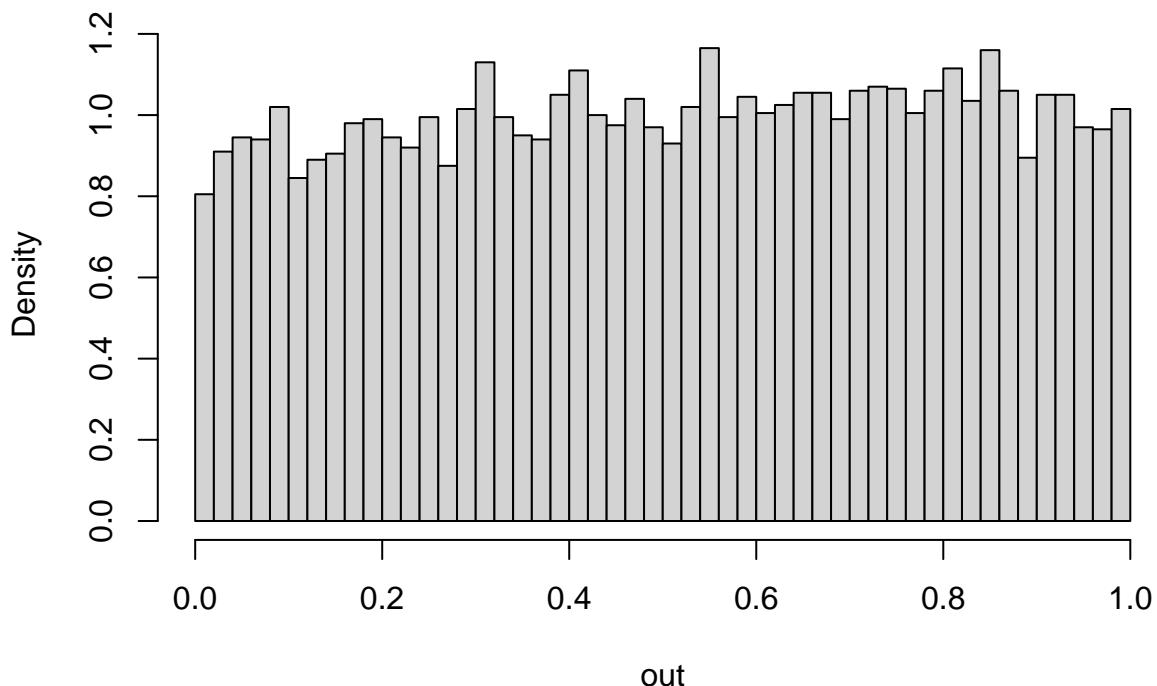

The Ljung-Box test Ljung and Box (1978) can be more powerful than the Box and Pierce test

```

out <- numeric(10000)
for (i in 1:10000) out[i] <- Box.test(rnorm(100), 4)$p.value
hist(out, 50, prob = T)

```

```

out <- Box.test(rnorm(100), 4)
Box.test(lm$residuals, 4)

```

### Checking Stationarity and Causality

Consider the following AR(4) process

$$\eta_t = 2.7607\eta_{t-1} - 3.8106\eta_{t-2} + 2.6535\eta_{t-3} - 0.9238\eta_{t-4} + Z_t,$$

the AR characteristic polynomial is

$$\phi(z) = 1 - 2.7607z + 3.8106z^2 - 2.6535z^3 + 0.9238z^4$$

```
# calculate the roots of the polynomial, and store in xi
